

I want to share a brief market analysis of our main digital payment platforms worldwide. First, I will show you four types of platforms, then describe their advantages and disadvantages, and summarize all users' common pain points.

The first kind of platform is C2C or P2P platforms, such as PayPal and Venmo. These services make it very easy for two people to transfer money directly, and they operate in many countries, which means they have a large global user base. On the other hand, they often charge high transaction fees, and sometimes accounts can be frozen without warning. Although the platform may review transactions, they are not fully visible on a public chain, so users must trust the company.

Secondly, we turn to B2C e-commerce payment systems like Stripe and Alipay. These platforms provide merchants with a complete suite of services, including invoicing, settlement, and reconciliation, and they integrate seamlessly into online stores. However, they charge a percentage of each sale, and merchants cannot trace the full path of funds once they leave the platform. As a result, small and medium businesses sometimes have the high entry cost.

Next, let us examine cross-border payment services such as Wise and Remitly. These services typically offer lower fees than traditional banks, and they send money very quickly, giving users a good overall experience. Nevertheless, they still depend heavily on local fiat-菲亚特 currency networks and must comply with complex regulations in each country. Therefore, they remain only partially decentralized.

Finally, we have centralized clearing networks like Visa and UnionPay. These networks are accepted nearly everywhere in the world and are extremely reliable thanks to their mature infrastructure. At the same time, their settlement cycles can be long—sometimes taking days—and the entire system is closed and controlled by a handful of clearing houses. Consequently, all transaction data is held by a few large organizations.

In conclusion, although each payment platform offers clear benefits, today's market still struggles with several key issues. First, users do not truly own or control their own funds and data. Second, payment routes are not transparent, making verification difficult. Third, platforms can change their rules anytime, leaving users unprotected. Furthermore, there is no way for users to define custom incentive mechanisms or to quantify their own contributions. Finally, traditional loyalty points cannot be transferred between platforms, lack on-chain proof, and have poor interoperability.
